Lecture

Power Spectral Density Estimation

EE 570: Location and Navigation

Lecture Notes Update on March 3, 2014

Aly El-Osery, Electrical Engineering Dept., New Mexico Tech Stephen Bruder, Electrical & Computer Engineering, Embry-Riddle Aeronautical University

Motivation

Sensors suffer from noise effects that can not be removed through calibration, consquently, we need to

- understand the nature of the noise
- be able to extract parameters from actual data
- develop models to mimic noise in simulation to provide performance capabilities

Purpose

Estimate the distribution of power in a signal. Unfortunately, truth and what is practical cause a problem.

Truth

- Infinitely long.
- Continuous in time and value.
- Provides true distribution of power.

Practice

- Finite length.
- Discrete in time and value.
- Only approximation of distribution of power.

Let's make it more interesting

The signal is stochastic in nature.

1 Review Material

1.1 Signal Classification

Energy and Power

Assume the voltage across a resistor R is e(t) and is producing a current i(t). The instantaneous power per ohm is $p(t) = e(t)i(t)/R = i^2(t)$.

Total Energy

$$E = \lim_{T \to \infty} \int_{-T}^{T} i^2(t) dt \tag{1}$$

Average Power

$$P = \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} i^2(t) dt \tag{2}$$

Arbitrary signal x(t)

Total Normalized Energy

$$E \triangleq \lim_{T \to \infty} \int_{-T}^{T} |x(t)|^2 dt = \int_{-\infty}^{\infty} |x(t)|^2 dt$$
 (3)

Normalized Power

$$P \triangleq \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} |x(t)|^2 dt \tag{4}$$

- x(t) is an *energy signal* iff $0 < E < \infty$, so that P = 0.
- x(t) is a power signal iff $0 < P < \infty$, so that $E = \infty$.

1.2 Time Averages

Correlation

For Energy Signals

$$\phi(\tau) = \int_{-\infty}^{\infty} x(t)x(t+\tau)dt \tag{5}$$

Provides a measure of similarity or coherence between a signal and a delayed version of itself. Note that $\phi(0) = E$

For Power Signals

$$R(\tau) = \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} x(t)x(t+\tau)dt \tag{6}$$

For Periodic Signals

$$R(\tau) = \frac{1}{T_0} \int_{T_0} x(t)x(t+\tau)dt \tag{7}$$

1.3 Frequency Domain

Energy Spectral Density

Rayleigh's Energy Theorem or Parseval's theorem

$$E = \int_{-\infty}^{\infty} |x(t)|^2 dt = \int_{-\infty}^{\infty} |X(F)|^2 dF$$
 (8)

Energy Spectral Density

$$G(F) \triangleq |X(F)|^2 \tag{9}$$

with units of *volts*²-*sec*² or, if considered on a per-ohm basis, *watts-sec/Hz=joules/Hz*

Power Spectral Density

$$P = \int_{-\infty}^{\infty} S(F)dF = \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} |x(t)|^2 dt$$
 (10)

where we define S(F) as the power spectral density with units of watts/Hz. Note that $R(0) = \int_{-\infty}^{\infty} S(F) dF$.

2 Random Signals and Noise

Basic Definitions

- Define an *experiment* with random *outcome*.
- Mapping of the outcome to a variable ⇒ random variable.
- Mapping of the outcome to a function ⇒ random function.

2.1 Statistical Averages

Probability (Cumulative) Distribution Function (cdf)

$$F_X(x) = \text{probability that } X \le x = P(X \le x)$$
 (11)

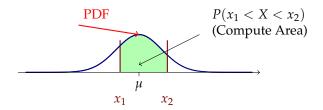

Describes the manner random variables take different values.

Probability Density Function (pdf)

$$f_X(x) = \frac{dF_X(x)}{dx} \tag{12}$$

and

$$P(x_1 < X \le x_2) = F_X(x_2) - F_X(x_1) = \int_{x_1}^{x_2} f_X(x) dx$$
 (13)

PDF of Discrete Random Variables

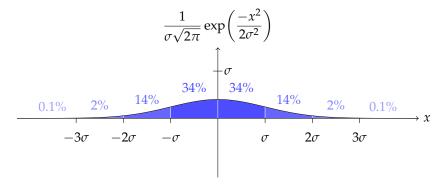

If the random variable X takes a set of discrete values x_i with probability p_i , the pdf of X is expressed in terms of Dirac delta functions, i.e.,

$$f_X(x) = \sum_i p_i \delta(x - x_i)$$
 (14)

Gaussian Distribution

$$f_X(x) = \frac{1}{\sigma_x \sqrt{2\pi}} \exp\left[-\frac{x - \mu_x}{2\sigma_x^2}\right]$$
 (15)

For example if $\sigma_x = \sigma$ and $\mu_x = 0$

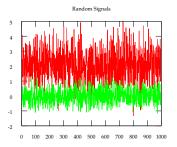

.13

.10

.11

PDF of White Noise

Mean and Variance

Mean of a Discrete RV

$$\bar{X} = \mathbb{E}[X] = \sum_{j=1}^{M} x_j P_j \tag{16}$$

Mean of a Continuous RV

$$\bar{X} = \mathbb{E}[X] = \int_{-\infty}^{\infty} x f_X(x) dx \tag{17}$$

Variance of a RV

$$\sigma_X^2 \triangleq \mathbb{E}\left\{ [X - \mathbb{E}(X)]^2 \right\} = \mathbb{E}[X^2] - \mathbb{E}^2[X]$$
 (18)

Covariance and Autocorrelation

Given a two random variables *X* and *Y*.

Covariance

$$\mu_{XY} = \mathbb{E}\left\{ [X - \bar{x}][Y - \bar{Y}] \right\} = \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y]$$
(19)

Correlation Coefficient

$$\rho_{XY} = \frac{\mu_{XY}}{\sigma_X \sigma_Y} \tag{20}$$

Autocorrelation

$$\Gamma_X(\tau) = \mathbb{E}[X(t)X(t+\tau)] \tag{21}$$

2.2 Stochastic Processes

Terminology

See Figure 1

- $X(t, \zeta_i)$: sample function.
- The governing experiment: random or stochastic process.
- All sample functions: ensemble.
- $X(t_i, \zeta)$: random variable.

Strict Sense Stationarity

If the joint pdfs depend only on the time difference regardless of the time origin, then the random process is known as *stationary*.

For stationary process means and variances are independent of time and the covariance depends only on the time difference.

.14

.15

.16

.17

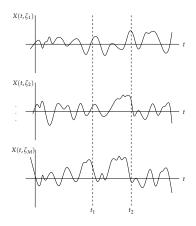

Figure 1: Sample functions of a random process

Wide Sense Stationarity

If the joint pdfs depends on the time difference but the mean and variances are time-independent, then the random process is known as *wide-sense-stationary*.

Ergodicity

If the time statistics equals ensemble statistics, then the random process is known as *ergodic*.

Any statistic calculated by averaging of all members of an ergodic ensemble at a fixed time can also be calculated by using a single representative waveform and averging over all time.

2.3 Correlation and Power Spectral Density

Power Spectral Density

Given a sample function $X(t, \zeta_i)$ of a random process, we obtain the power spectral density by

$$S(F) \stackrel{\mathcal{F}}{\longleftrightarrow} \Gamma(\tau)$$
 (22)

i.e., for a wide sense stationary signal, the power spectral density and autocorrelation are Fourier transform pairs.

2.4 Input-Output Relationship of Linear Systems

Input-Output Relationship of Linear Systems

$$x(t) \longrightarrow H(F) \longrightarrow y(t)$$

$$S_Y(F) = |H(F)|^2 S_X(F) \tag{23}$$

Noise Shaping

If x(t) is white noise, we can design the filter h(t) to "shape" the noise.

.19

.20

.21

3 Discrete Signals and Systems

.23

Sampling Remarks

- Must sample more than twice bandwidth to avoid aliasing.
- \bullet FFT represents a periodic version of the time domain signal \to could have time domain aliasing.

 $\Delta F = 1/T_0$

• Number of points in FFT is the same as number of points in time domain signal.

.24

4 Power Spectral Density

Obtaining PSD for Discrete Signals

What we want is

$$\Gamma_X(\tau) = \mathbb{E}[X(t)X(t+\tau)] \xrightarrow{\mathcal{CTFT}} S_X(F)$$

For infinitely long signals.

What we can compute is

$$\gamma_X(m) = \mathbb{E}[X(n)X(n+m)] \xrightarrow{\mathcal{DFT}} P_X(f)$$

For finite length signals.

.25

What do we need in an estimate

As $N \to \infty$ and in the mean squared sense

Unbiased

Asymptotically the mean of the estimate approaches the true power.

Variance

Variance of the estimate approaches zero.

Resulting in a consistent estimate of the power spectrum.

Possible PSD Options

Periodogram

computed using 1/N times the magnitude squared of the FFT

$$\lim_{N\to\infty} \mathbb{E}[P_X(f)] = S_X(f)$$

$$\lim_{N \to \infty} var[P_X(f)] = S_X^2(f)$$

Welch Method

computed by segmenting the data (allowing overlaps), windowing the data in each segment then computing the average of the resultant priodogram

$$\mathbb{E}[P_X(f)] = \frac{1}{2\pi MU} S_X(f) \circledast W(f)$$
$$var[P_X(f)] \approx \frac{9}{8L} S_X^2(f)$$

Welch Method

Assuming data length N, segment length M, Bartlett window, and 50% overlap

- FFT length = $M = 1.28/\Delta f = 1.28F_s/\Delta F$
- Resulting number of segments = L = ^{2N}/_M
 Length of data collected in sec. = ^{1.28L}/_{2ΔF}

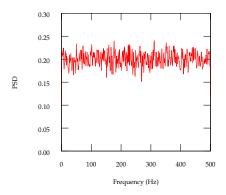

pwelch Function

```
[Pxx,f] = pwelch(x,window,noverlap,...
                 nfft,fs,'range')
```

You can use [] in fields that you want the default to be used.

pwelch Function - WGN signal

```
Fs = 1000;
x = sqrt(0.1*Fs)*randn(1,100000);
[Pxx,f] = pwelch(x,1024,[],[],Fs,'onesided');
```

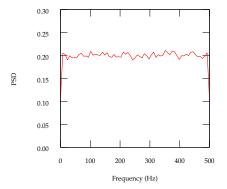

Variance to high.

.27

.29

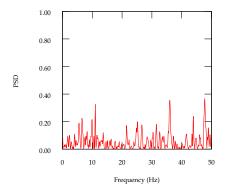

pwelch Function - WGN signal

```
[Pxx,f] = pwelch(x,128,[],[],Fs,'onesided')
```

- Reduced window size.
- Variance is now smaller.

pwelch Function - cos + WGN signal

- Window larger than length of data.
- Frequency components can't be resolved.
- Variance high.

pwelch Function - cos + WGN signal

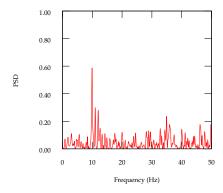

```
Fs = 100; t = 0:1/Fs:5;

x = cos(2*pi*10*t)+cos(2*pi*11*t)+...

sqrt(0.1*Fs)*randn(1,length(t));

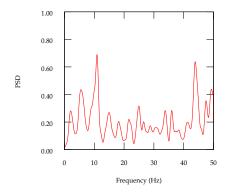

[Pxx,f] = pwelch(x,1024,[],4096,Fs,'onesided');
```

.31

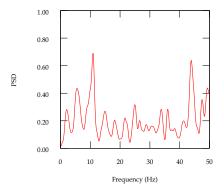

• As expected increasing nFFT does not help.

pwelch Function - cos + WGN signal

- Decreasing the window size decreases the variance.
- Still can't resolve the two frequencies.

pwelch Function - cos + WGN signal

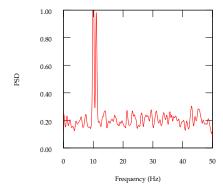

.33

.34

9

- Length of data sequence must be increased.
- Still can't resolve the two frequencies as the window size is too small.

pwelch Function - $\cos + WGN signal$

• Now we can resolve the two frequencies.

Spectral Estimation - Remarks

- The length of the data sequence determines the maximum resolution that can be observed.
- Increasing the window length of each segment in the data increases the resolution.
- Decreasing the window length of each segment in the data decreases the variance of the estimate.
- nFFT only affects the amount of details shown and not the resolution.
